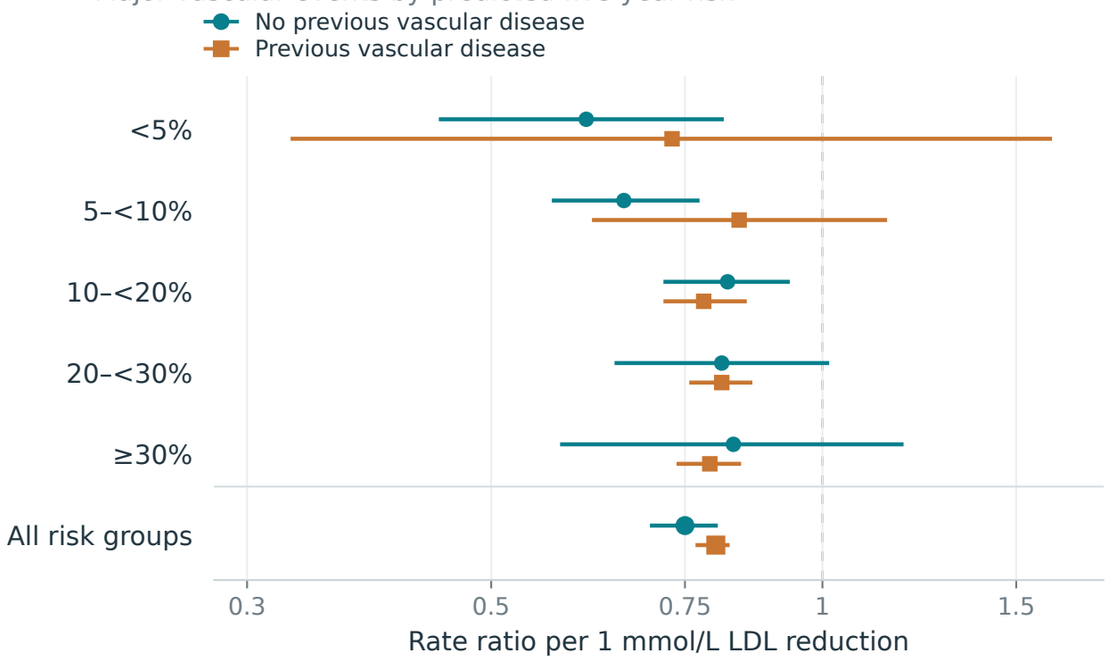
Statins before a first cardiovascular event

Published evidence and a reproducible trial-level check

A Benefit is present before established vascular disease

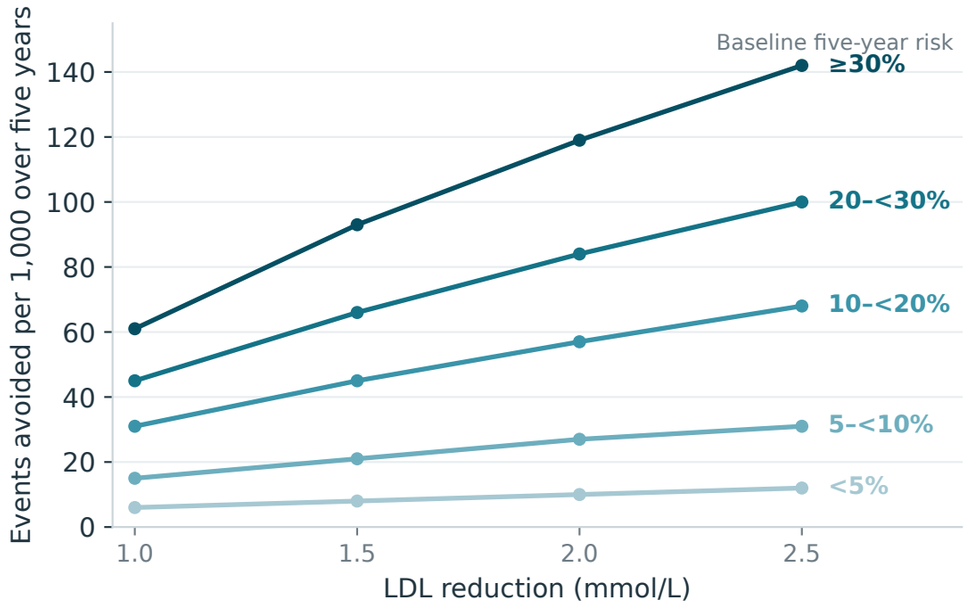
Major vascular events by predicted five-year risk



Strata: 99% intervals; summaries: 95%. CTT 2012, Figure 2.

B Absolute benefit increases with baseline risk

Published projections, expressed without 3D perspective



Model projections for both prevention settings. CTT 2012, Figure 5.

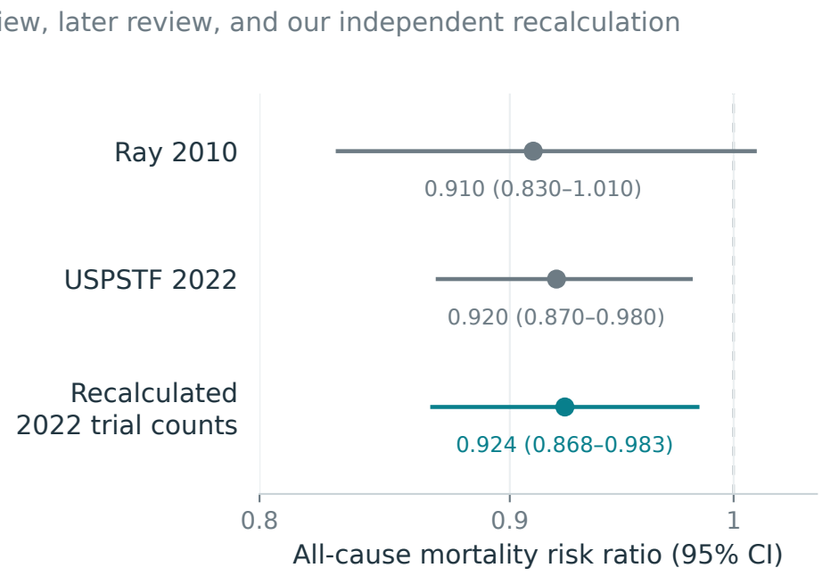
C First-event prevention and mortality are different outcomes

Primary prevention review; published pooled estimates

Observed follow-up differs by trial (1–6 years for these outcomes).
Absolute effects overlap; do not add them. Chou et al., 2022.

D Similar mortality estimates can yield different certainty

Earlier review, later review, and our independent recalculation



Reanalysis: 0.924 (0.868–0.983); heterogeneity I^2 = 0%.
Overlapping reviews are compared, not pooled together.

A–C redraw published estimates or projections; D includes a new aggregate-data calculation. No individual participant data. The 2022 synthesis is not an update through 2026.
